

Case Study:

A school has installed a **Smart Entry System** at its main gate. Every morning, the system checks a student's ID number before allowing them to enter. For this activity, the school has decided that students with **ID numbers greater than or equal to 1000** are allowed to enter through the main gate, while students with **ID numbers below 1000** must report to the school office.

The school wants to automate this process using a Python program.

Your Task:

Read the case study and answer the following questions before learning the `if` statement.

1. What information (input) does the program need from the user?
2. What condition should the program check?
3. What should the program display if the condition is true?
4. What should the program do if the condition is false?
5. Write the condition in plain English (without using Python syntax).
6. Predict the output for the following ID numbers:
 - 1250
 - 980
 - 1000

Think and Discuss:

- Why is a condition needed in this situation?
- Can you think of other real-life systems that make decisions based on a condition?
